

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

lack at present, and at the same time to develop the resources of the country. In order to make the work of such a survey as useful as possible, it is proposed to make the results known through the agency of the daily press and other publications, to be issued as rapidly as possible. It is to be hoped that the practical and wise measures proposed by the association will be carried out, as they cannot fail to benefit the people of the State.

LETTERS TO THE EDITOR.

* * * Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.

Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

The editor will be glad to publish any queries consonant with the character of the journal.

Is the Rainfall increasing on the Plains?

IN view of the recent discussion on this subject which has appeared in this periodical, perhaps it will not be amiss to add a few remarks to those of Mr. Curtis concerning the errors which may arise in climatic studies from errors in rainfall records. Rainfall records have probably been kept as long in New England as in any other part of the United States, and a number of them give indications of a secular change in the amount of rainfall. But Mr. E. B. Weston, Desmond Fitzgerald, and others who have had occasion to study some of these records, state that in certain cases the apparent change in the amount of rainfall was clearly due to the different methods pursued by different observers in measuring snow, and converting it to its equivalent in rain; and they think but little reliance can be put in the results obtained from a comparison of earlier with more recent records. Mr. Weston has also shown that gauges with different kinds of rims give persistently different results. If these early volunteer records are of uncertain value for studying climatic changes, are those which are now being gathered by our national Signal Service to prove more so? These latter records are in almost every case obtained from rain-gauges exposed on the roofs of houses; and hence the amount of rain caught becomes a function of the wind-velocity, a function of the wind-direction, and a function of other variants and variables, not least among which is a not uncommon change in the position of the gauge itself. Numerous experimental observations have shown that gauges exposed on roofs catch more rain when exposed on the side opposite to the direction from which the wind blows, and less rain when exposed on the same side from which the wind blows. The writer thought that the large errors which may arise from this source were fully recognized by the Signal Service officers and by the scientific public, so that it was unnecessary to call attention to them. But recently he has listened to two papers by well-known writers, dealing with changes in the amount of rain, especially in the West; and both these writers referred to the valuable records now being obtained by the Signal Service as furnishing a basis for future studies of this kind. The present writer inferred from these papers that the errors arising from exposure are not so fully known as they ought to be, and hence presents a brief study of the Boston rainfall record, which is only one of several similar cases which have come under his notice. For several years in succession the annual rainfall at the Boston Signal Service station has been reported below the normal. According to the Bulletin of the New England Meteorological Society, in 1885 it was nearly three inches below the normal, in 1886 nearly five inches, and in 1887 nearly thirteen inches below. This seemed rather strange, since none of the numerous gauges around Boston showed such marked deficiencies. Thus, in 1887, when the Boston Signal Service station reported the annual rainfall thirteen inches below normal, the Harvard College Observatory, only three miles west of Boston, reported an annual rainfall twelve inches greater than that reported from Boston, and one inch greater than the average of twenty years' observations at the observatory. The observer at Lynn, Mass., ten miles north of Boston, reported an annual rainfall fifteen inches greater than Boston, and six inches above the average of thirteen years' observations at Lynn. According to the records of several gauges in Milton, ten miles south of Boston, the annual rainfall was from nine to twelve inches greater than at the Boston station. These stations are all so close to

Boston, that it is rendered entirely improbable that there was in reality any great deficiency in the Boston rainfall; and the apparent deficiency seems clearly due to a change in the position of the Boston gauge about 1883 or 1884. Previous to this the gauge had been exposed on the roof of the Equitable Building in Boston, and these records were used in forming a series of averages or normals. Then the gauge was removed to a high tower on the Post-Office Building, and since then there has been almost a persistent deficiency of precipitation as compared with former records, or with the records of stations surrounding Boston. Moreover, the amount of rainfall caught is evidently a function of the wind-velocity, and decreases with increased velocity of the wind. Thus, during a gale on April 2, 1887, the amount of precipitation reported from the Boston Signal Service station was 0.22 of an inch; while measurements by a number of observers in and around Boston showed that snow fell to a depth of over a foot, and when melted gave an inch of precipitation as ordinarily recorded. Again, during the storm of March 11 to 14, 1888, the Boston Signal Office reported 1.24 inches of precipitation, while surrounding stations reported three inches or more.

It seems a pity that our Signal Service gauges should be so badly exposed, for these are looked to as the standards throughout the country; and there is no doubt that in the future, as in the past, there will be attempts to prove climatic changes from their records; but the writer feels that any one who has had experience with rainfall observations will look dubiously on any conclusions based on such records as exist at present.

H. HELM CLAYTON.

Blue Hill Observatory, May 2.

Significance of Sex.

SOME recent publications on the subject of the significance of sexual reproduction, especially those of Dr. Weissmann (*Nature*, xxxiv. p. 629, 1886, and xxxvi. p. 607, 1887) and a short abstract of a lecture by Hatschek (*Annals and Magazine of Natural History*, i. p. 163, 1888), have induced me to draw brief attention to some speculations of my own on this subject, published several years ago.

1. Dr. Weissmann, in his admirable paper on the significance of polar globules (*Nature*, xxxvi. p. 607, 1887), after showing that there must be some very great benefits resulting from the introduction of sexual reproduction, says, "Such beneficial results will be found in the fact that sexual propagation may be regarded as *the source of individual variability, furnishing material for natural selection.*" Now, in an article on genesis of sex, published in the *Popular Science Monthly*, December, 1879 (xvi. p. 167), and republished in the *Revue Scientifique* for Feb. 14, 1880 (xviii. p. 220), the same thought is distinctly implied, though not distinctly expressed. The whole contention of the article is to show that the object of sex is the funding of individual differences in a common offspring, thereby improving the offspring; and, further, to show how much pains nature has taken to make individual sexual differences greater and greater in the history of evolution. In the last paragraph I say, "Such mixing produces more *plastic nature*, more generalized, and therefore more progressive form."

This was written nearly nine years ago. Meanwhile the thought continued to develop in my mind. In a book ('*Evolution and its Relation to Religious Thought*') just now published, but most of which, and especially all on this subject, was written three years ago, the same thought is much more distinctly expressed. On p. 220 I say, "Why was sex introduced at all? There are doubtless sufficient reasons of many kinds, but the *fundamental reason connected with evolution is the funding of individual differences in a common offspring, thereby giving to the offspring a tendency to divergent variation.*" Again on p. 223: "*Complexity of inheritance, like complexity of composition in chemical substances, gives instability to the embryo and liability to variation to the offspring; and this in its turn furnishes material for selection of the fittest.*" This was written in the fall of 1884; but, being much pressed with other work at that time, I laid aside the manuscript, and only took it up again, finished it, and sent it to the publisher, about a year ago. I do not bring this forward now by way of reclamation, — for even if I had any right to make such, which I have not, I care little who brings out a truth, — but partly because I would not seem to borrow an
